1 Some Questions Remained

1.1 What is Forward and Back propagation?

In short, forward propagation is a way we used to count the value of compound functions. And back propagation is used to count the derivative of compound functions. We needn't complicate them.

1.2 How can we express the derivative of $\sigma(z)$?

By taking the derivative of $\sigma(z)$, we can easily get the result: $\sigma'(z) = \sigma(z)(1 - \sigma)$. Further, we can gain the consequence:

$$dz = \frac{\partial L}{\partial z} = \frac{\partial L}{\partial a} \cdot \frac{\partial a}{\partial z} \quad (1)$$

$$= \left(-\frac{y}{a} + \frac{1-y}{1-a}\right) \cdot a(1-a) \quad (2)$$

$$= a - y \quad (3)$$

$$dw = \frac{\partial L(w, b)}{\partial w} = \frac{\partial L}{\partial z} \cdot \frac{\partial z}{\partial w} \quad (4)$$

$$= dz \cdot x \quad (5)$$

$$= x(a - y) \quad (6)$$

$$db = \frac{\partial L}{\partial b} = \frac{\partial L}{\partial z} \cdot \frac{\partial z}{\partial b} \quad (7)$$

$$= 1 \cdot dz \quad (8)$$

$$= a - y \quad (9)$$

1.3 Some uses of numpy. ²

1. Create a vector:

```
1 x = np.array([...])
```

2. Call some frequently-used functions

```
1 np.exp(x)
2 np.log(x)
```

²The source of package "pythonhighlight": <https://github.com/chenfeng1234/pythonhighlight>

3. Get the shape of matrices

```
1 x.shape[0] # the number of rows
2 x.shape[1] # the number of column
```

4. Change the dimension

```
1 x.reshape((row,col))
```

5. Count the length of each row

```
1 x_norm = np.linalg.norm(x, axis=1, keepdims =
                             True)
```

6. Matrix-matrix or matrix-vector multiplication

```
1 # matrix multiplication:
2 # x1.shape = (a, m), x2.shape = (m, b)
3 np.dot(x1,x2)
4 # multiply the elements in corresponding
                           locations
5 # x1.shape = (a, m), x2.shape = (a, m)
6 np.multiply(x1, x2)
```

7. Gain random numbers

- Get one number

```
1 n = numpy.random.random()
```

- Get a matrix

```
1 n = numpy.random.random(size=(3, 2))
```

- Generate random numbers between 0 and 1

```
1 np.random.rand(2,3) # (2,3) show the  
                        dimension
```

- Generate the same random numbers

```
1 '''  
2 Set the same seed every time,  
3 and we can get the same random numbers  
4 '''  
5 numpy.random.seed(num)  
6 numpy.random.rand(the_length_of_the_array)
```

1.4 What do high bias and high variance mean?

High bias means that your model can't fit your train set well and high variance means your model

overfit the train set so that it can't fit other data well.

Figure 1: Overfitting

Figure 2: Underfitting

1.5 How does regularization prevent overfitting?

Regularization is able to reduce overfitting by adding the regularization term, $\frac{\lambda}{2m} ||w||_2^2$. So the derivative $\frac{\partial L}{\partial W}$ turns into: $dW^{[l]} = (form_backprop) + \frac{\lambda}{m} W^{[l]}$. Then we can get the update of grads as fol-

lows:

$$W^{[l]} := W^{[l]} - \alpha[(form_backprop) + \frac{\lambda}{m}W^{[l]}] \quad (10)$$

$$= W^{[l]} - \alpha\frac{\lambda}{m}W^{[l]} - \alpha(form_backprop) \quad (11)$$

$$= (1 - \frac{\alpha\lambda}{m})W^{[l]} - \alpha(form_backprop) \quad (12)$$

If λ is big enough, the weight matrix W can be very small, and so does the Z . As the Figure 3 shows, when Z is relatively small, $\tanh(Z)$ could be almost linear. We have known that when $g(x)$ is linear, no matter how deep the neural network is, what it counts is always a linear function which can't fit very complicate data.

Of course we need't keep Z so small all the time, but we can find a reasonable range that makes our model "just right".
